Cooling solar Inverter

Overview

Can solar inverters be cooled?

Solar inverters can be cooled in one of two ways: by using a passive cooling system or through active cooling. Passive or natural cooling means that the inverter's cooling fin dissipates heat without the need for a fan. This lack of air circulation leads to hotspots of warm air, which reduce the lifespan of the solar inverter.

How does solar inverter cooling work?

In order to keep the heat low, the inverter will stop generating power or reduce the amount of power it generates by "derating" as it passes programmed temperature milestones. Solar inverters can be cooled in one of two ways: by using a passive cooling system or through active cooling.

Why do solar inverter cooling systems use heat sinks?

In the solar inverter cooling system, heat sinks are mainly used to expand the heat dissipation area of the radiator surface to achieve the purpose of strengthening heat transfer. The choice of the material of the radiator itself has a direct relationship with its heat dissipation performance.

Why do solar inverters need active cooling?

Active cooling lowers the temperature by effectively cooling all of the electrical components and heat sinks, reducing hot spots. This reduces component strain, which extends solar inverter component life. The inverter's cooling fan is crucial since power generation is dependent on heat dissipation performance.
