# How much stress does solar tempered glass have

## Overview

---

How much stress does tempered glass have?

The residual stress determines the strength of the glass. According to the American standard ASTM C1048, the stress in a tempered glass surface should be greater than  $6.9 \times 10^7$  Pa. For half-tempered glass, it can be  $2.4-5.2 \times 10^7$  Pa. For a given set of tempering conditions, the internal stress distribution varies with the glass thickness.

How to assess thermal stress in glass?

Assessing thermal stress in glass is up to now not usual. Only experienced manufacturers or architects who are specifying a thermal stress analysis are taking care about that topic. Thermal glass stress analysis should be always done in relation to the structural calculations of glass.

How does thickness affect temperature and stress distribution during glass tempering?

Thickness has influence on temperature and stress distribution during glass tempering. For thin glass, increase heat transfer to obtain sufficient  $\Delta T$ , but  $\Delta t$  is very short. It is relatively difficult to fully temper thin glass. To achieve thinner tempered glass, it is necessary to clarify the stress change during its quenching process.

What is the risk of glass breakage due to thermal stress?

2.1. Risk of glass breakage due to thermal shock Thermal stress is caused by temperature differences on the glass pane. If the temperature difference is sufficiently great, the thermal stress can cause breakage to develop from the edge of the glass.
