Npc inverter current and voltage loop control

Overview

The NPC converter control model developed in Simulink can be downloaded below. Both versions only differ in the modulation technique (carrier-based or space vector modulation).

The circuit is shown in Fig. 1. The NPC is built from 3 PEN8018 modules. They are controlled by the B-Box RCP, and the control code is developed with the ACG SDK on Simulink (a valid license is required). This example uses a passive filter box (for the inductors and the EMC filter), a grid connection panel, and an 800V DC source. The grid voltages are measured with DIN800V voltage sensors. The wiring of the gating signals and the measurements between the PEN modules and the B-Box controller is identical to that of Getting started with an NPC converter. The wiring of the power stage can be done.

Experimental results measured at nominal operation are shown in Fig. 6, where the current reference for the d-axis is set to 6A at $t=0$, 15A at $t=50\text{ms}$ and 10A at $t=100\text{ms}$. As expected, the reference is well followed, resulting here in an injected current in phase with the grid voltage, since the q-axis current reference is set to zero.

What is closed-loop current control for a grid-tied neutral point clamped (NPC) inverter?

This page provides an example of closed-loop current control for a grid-tied Neutral Point Clamped (NPC) inverter. The considered setup is a three-phase three-wire NPC inverter supplied by a DC source and connected to the grid.

What is a 3L NPC inverter?

These benefits are fulfilled by the three-level neutral point-clamped (3L-NPC) inverter, making it a highly suitable option for PMSM system applications requiring high power and high voltage. In such applications, field-oriented control (FOC) and direct torque control (DTC) are the two predominant methodologies.

What is a 3 level NPC inverter?

A fundamental configuration of the PMSM supplied by three-level NPC inverters is depicted in Fig. 1. Each phase leg of the NPC inverter features four semiconductor switches and two clamping diodes. A split DC-link capacitor that divides the DC voltage into two equal halves, creating the neutral point (o).

Can a three-level neutral point clamped inverter drive a permanent magnet synchronous motor?

This research presents an enhanced model predictive current control strategy for a three-level Neutral Point Clamped inverter driving a permanent magnet synchronous motor. The proposed new strategy significantly reduces computational complexity and balances the DC-bus capacitor voltages without weighting factors.
