The voltage rises when the inverter is working

Overview

Why does a solar inverter need a voltage rise?

Voltage rise is necessary in selling energy from your solar system to the grid. When the voltage at your inverter is much higher than that of the grid, the energy will normally try to find its way into the grid.

How do you calculate solar inverter voltage rise?

For example, if the grid voltage is 230V and the solar inverter gives 235V, then the voltage rise is 5V. This is done by subtracting the grid voltage from the output of the inverter: $235\text{V (solar inverter)} - 230\text{V (grid)} = 5\text{V}$. The inverter needs this small voltage rise so that energy can flow from your home to the grid. Why is Voltage Rise Important?

.

How does a solar inverter work?

Alternatively, there's a 5V voltage drop from the inverter to the grid. For electricity to flow from the inverter to the grid (to export excess solar energy generated), there must be a small voltage rise from the grid to the inverter, to "push" the energy from your inverter to the grid.

How high can an inverter be above the grid?

The inverter must therefore have a higher voltage than the grid, but only by a small amount: typically no more than 2% above the grid's voltage. For example, in Australia, where the standard grid voltage is 230V, a 2% rise means that the inverter voltage can rise to at least 4.6V above the grid, or to 235.6V.

In which situation does the voltage rise?

For a voltage rise to occur, the solar inverter potential must be greater than the grid potential (as in option b), hence, this option partially supports voltage rise.
